A How a task is scored

1 Graph

FlyWire v783, one of three pinned builds:

- Codex ≥5, reference
- Codex, blank transmitters signed
- Shiu et al. 2024 graph

or a shuffled control of it (rewired, random, sign-flip)

2 Model

the same LIF for every neuron (Shiu et al. 2024), one global gain

or any submitted model through the adapter

3 Task (one YAML file)

stimulus: sugar GRNs, 100 Hz
readout: MN9 (proboscis)
check: MN9 rate > threshold
basis: the cited experiment, or "convention"
conditions: drive, silence, mix

4 Score

pass: on every seed
graded: sigmoid of the log margin, 0.5 at the threshold
specificity: real wiring minus best control

Pre-registration: an RFC commits predictions before the first run on real wiring; the outcome is recorded beside them, wrong ones included.
